COMMISSIONING COSY COOLER WITH ELECTRON BEAM AT NOVOSIBIRSK

BINP, Novosibirsk, Russia

Abstract

The electron cooler of a 2 MEV for COSY storage ring FZJ is assembled in BINP [1]. Results of experiments with high voltage, with electron beam, cascade transformer for distribution power along acceleration tube will be discussed in this report. The COSY cooler is designed on the classic scheme of low energy coolers like cooler CSRm, CSRe, LEIR that was produced in BINP before. The electron beam is transported inside the longitudinal magnetic field along whole trajectory from an electron gun to a collector. This optic scheme is stimulated by the wide range of the working energies 0.025-2 MeV. The electrostatic accelerator consists of 33 individual unify section. Each section contains two HV power supply (plus/minus 30 kV) and power supply of the magnetic coils. The electrical power to each section is provided by the cascade transformer. The cascade transformer is the set of the transformers connected in series with isolating winding.

SETUP DESCRIPTION

A new generation of accelerators to study nuclear physics in the range of relativistic physics 1-8 Gev/u will require very powerful cooling to obtain high luminosity. For example the experiments with 15 GeV antiprotons for investigation of meson resonances on PANDA detector require an internal hydrogen target with effective thickness 4×10^-3 hydrogen atoms per cm^2 and 10^{-10} – 10^{-11} antiprotons circulating in HESR. In this case the peak luminosities ranging from 2×10^{31} to 2×10^{32} cm^{-2}s^{-1} are achievable. Resolution of the experiments is limited only by momentum spread in antiproton beam, which must be better than 10^{-5}. These experiments demand the strong system of the “cooling” of the antiproton beam for suppression of the internal target influence. The electron cooler for COSY storage ring may be prototype of such system.

The basic idea of this cooler is to use high magnetic field along all orbit of the electron beam from the electron gun to the electron collector. At this case we have chance to have high enough the electron beam density at cooling section with low effective temperature. For example the electron beam density 2×10^{8} cm^{-3} (beam diameter 6 mm and current 1.5 A) magnetized with longitudinal magnetic field 2 kG will have at beam reference system drift velocity 2.7×10^{6} cm/sec. This velocity lets (at principle) to have cooling time near 0.1 sec for the beam with low angular spread Δp_{θ} / p =10^{-5}.

The schematic design of the setup is shown in Fig.1. The electron beam is accelerated by an electrostatic generator that consists of 33 individual sections connected in series. Each section has two high-voltage power supplies with maximum voltage 30 kV and current 1 mA. The electron beam is generated in electron gun immersed into the longitudinal magnetic field. After that the electron beam is accelerated, moves in the transport line to the cooling section where it will interact with protons of COSY storage ring. After interaction the electron beam returns to electrostatic generator where it is decelerated and absorbed in the collector.

The optics of 2 MeV cooler for COSY is designed close to the classical low-energy coolers. The motion of the electron beam is magnetized (or close to magnetized conditions) along whole trajectory from a gun to a collector. This decision is stimulated by requirement to operate in the wide energy range from 25 keV to 2 MeV. So, the longitudinal field is higher then transverse component of the magnetic fields. The bend magnets and linear magnets of the cooler are separated by a section with large coils for the location of the BPMs, pumps and a comfort of the setup assembling. The length of the linear magnets is defined by the necessity to locate the electrostatic generator outside the shield area of the storage ring.

The vacuum chamber is pumped down by ion and titanium sublimation pumps. The typical diameter of the vacuum chamber is 100 mm and the aperture in the transport channel and cooling section is close to this value. The diameter of the accelerating tube is 60 mm.

The main subsystem of the electron cooler are 1 electrostatic accelerator, 2 high voltage terminal, 3 main magnetic system, 4 Corrector magnetic system, 5 Interlock system, 6 Cascade Transformer power supply, 7 BPM system, 8 Oil system, 9 SF6 system, 10 Magnetic probe system
MAGNETIC SYSTEM

The magnetic field in the accelerating tube is taken 500 G and this value is related to the maximum power that can be transfer to a high voltage potential with help of the cascade transformer. The value in the transport channel is located in the range 0.5 kG – 1 kG. The energy 2 MeV is high enough in order to don’t have the complete adiabatic motion of the electrons because the magnetic field of the bend elements is chosen to provide the length of bend equal to integer number of Larmour lengths. In such case the kick on entry to bend is compensated by kick on leaving and the excitation of the transverse motion of the electron is small. So, it is convenient to change the longitudinal magnetic field according to the electron momentum. At attainment of the maximum magnetic field the transition to another integer number is implemented.

The magnetic field in the cooling section is taken 2 kG in order to have the maximum Larmour oscillation (~ 10) of the electron during its interaction with ion in order to have the magnetized Coulomb collisions even the highest electron energy 2 MeV.

The transition from accelerating tubes to transport channel is made with 7 coils powered by independent power supplies [2]. The transition from the transport channel to the cooling section is made with 5 coils with small regulation of the longitudinal current with regulated electrical shunt. In this region the magnetic field is strong and the electron motion is close to adiabatic so the matching can be realized by the proper location of these coils in order to minimize the amplitude of the transverse motion.

ELECTROSTATIC GENERATOR

The accelerating column consists of 33 identical high voltage sections [3]. The column with high voltage terminal is placed in special tank which was filled with SF6 under pressure up to 5 bar. The section contains two magnetic coils producing guiding magnetic field for acceleration and deceleration tubes and the high voltage power supply producing up to 60 kV. Total power consumption of one section is about 300 W. The coils and the electronic components are cooled with transformer oil. The sections were tested by the spark with voltage up to 1.5 MV without damage. The connection of the control program with each section was done with wireless ZigBee protocol. Because of the mesh topology this communication network shows the good stability at the operation inside the high voltage tank at the presence of corona and spark discharges.

Figure 2 shows the increase of corona current versus the high voltage applied to the accelerating column. The main reason of this current may be determined by sharp edge in welding of high voltage tank.
Figure 3 shows the dynamics of the high-voltage generator at the typical recuperation breakdown. In time of the breakdown the leakage current achieves the maximum value 1 mA and the voltage of the electrostatic generator drop down to zero level. This behaviour is useful because it helps to avoid the mechanical damage of the vacuum chamber induced by the electron beam heating. After detection of the maximum leakage current the control program closes the electron gun and the high-voltage is restored without problem.

**CASCADE TRANSFORMER**

The key problem of the accelerating/decelerating column is transfer energy to 33 sections, gun and collectors are located at high voltage potential. The base idea of the power supply is based on idea of a high frequency cascaded resonant transformer. The system consists of 33 transformers with cascaded connection. The electrical energy is transmitted from section to section from the ground to high-voltage terminal. Along this way the energy is consumed by the regular high-voltage section. The main problem of such decision is leakage inductance of the transformers. They are connected in series and the voltage from power supply is divided between leakage inductance and a useful load. In order to solve this problem the special compensative capacitance is used. The impedance of leakage inductance is decreased significantly on the resonance frequency. The leakage inductance of one section is 41 μH, the compensative capacitance is 0.94 μF, the effective resistance of the power loss is 0.12 Ohm per section.

A problem was discovered for such type transformer. The problem induced by use of the simple type rectifier as power supply of the electron collector. The non-resistive and non-linear load leads to large dropping down of the voltage on the top of the cascade transformer because the cascade transformer has a good transfer coefficient for the fixed frequency only. Using the capacitance as load of the cascade transformer solves this problem but it increases the reactive current. In principle the power supply of the collector with impedance correction may be appropriate decision. The experiments with the operation of the cascade transformer loaded by a resistor yielded a coefficient of voltage transfer of 0.9 at 25 kWt power loading.

Figure 4a shows distribution of the auxiliary power supplies along accelerated column. At no-load operation the maximum auxiliary voltage is 200 V. Switching on the coil current in the high-voltage sections (7.0 kWt) reduces auxiliary voltage to 150 V. Adding the collector loading (0.5 A current, 4 kV voltage) changes the auxiliary voltage to 125 V (see Fig. 4b). The range of variation of the auxiliary voltage is 125-200 V that is sufficient for the possibility of the modern electronics modules.

**DIAGNOSTICS**

The beam line is equipped with several types of the beam diagnostics. The electron beam trajectory is measured by 12 BPMs. The sinusoidal modulation with amplitude 10 V at frequency 3 MHz is applied to the control electrodes of the electron gun and the AC component of the electron current is added to its DC value. Two BPMs located in the cooling section can work with proton component also. They will be used for alignment of the electron and ion beams.

The effective cooling and beam passing requires the minimization of the electron angles and oscillation envelope of the beam. For this purpose the special electron gun with 4-sectors control electrode was designed and manufactured. The design of the gun is shown in Fig. 6. The modulation signal may be supplied to each sector of the control electrode. So, the position of one quadrant sector of the electron beam can be measured by BPM system. Comparing the positions of each sectors from BPM to BPM or the sector positions in the single BPM between the different values of the corrector coils it is possible to analyze the optics of the electron beam in the transport channel. Figure 5 shows the example of the measurement of the shape of the electron beam.

Figure 5: Measure of the electron beam position and the beam shape with 4-sectors electron gun.

Figure 6: Design of the electron gun and 4-sectors control electrode. The right picture shows the distribution of the electron current when the control voltage is applied to the single sector.

The control of the beam shape can be done independently by a set of the Faraday cups located in line05-4 (see Fig.7). The electron beam is shifted by the correctors on the diagnostics device. In order to minimize the load of the electrostatic generator the electron beam was modulated in the pulse mode (5 μs pulse at 20 Hz repetition rate). So, the electrostatic generator is able to work in nominal regime because the average DC current to the ground is small enough.

**ELECTRON BEAM PROPERTY**

The adjustment of the trajectory of the electron beam was done with corrector sets (see Fig. 7) that may be divided on four groups. The first group controls the centre of the electron beam (bends and line17 elements). The second group controls the passing beam with large gradient of the longitudinal magnetic field (match and torbnd elements). The third controls fast Larmour oscillation of the electron beam (line10 elements). This corrector has minimal longitudinal size and located in the nearest place to the vacuum chamber in order to have minimal longitudinal length of the magnetic field. The forth set is located in the cooling section and controls the convergence of ion and electron beams (cool element).

The experimental analysis of the influence of magnetic elements on the electron trajectory was done by diagnostics tools. The typical scheme of experiments consists of the excitation of motion by a magnetic element, the phase incursion of the Larmour rotation changing magnetic field in the cooling section (cool, see Fig.7) and the registration of the beam position by BPM. Figure 8 shows moving of the centre orbit at the different value of the dipole corrector.

Figure 9 shows the necessity matching the longitudinal magnetic field to the electron momentum in order to the action of the edge field on the input and output of bend magnet compensates each other. The difference of the longitudinal magnetic field from optimum value 570 G on 20 G leads to excitation of Larmour oscillation with amplitude about 2 mm.

Figure 7: Location of the BPM (marked by arrows) and magnetic elements of COSY cooler.

Figure 8: Larmour oscillation of the electron beam at the currents in the dipole correctors (line10-1). The numbers near curves are currents in the horizontal and vertical correctors. The electron energy is 1 MeV. The electron angle without correction is 40 mrad. The magnetic field in BPM region is 950 G.
The important parameter for the stable operation of the high-voltage cooler is low leakage current. At the beam current about 500 mA the relative value of the leakage current was $10^{-6}$ - $10^{-5}$ in the different electron energy range.

**SUMMARY**

1. The key problems of the electron cooler 2 MeV (modular approach of the accelerator column, the cascade transformer, the compass base probe located in the vacuum chamber, the design of the electron gun with 4-sectors control electrode) is experimentally verified during commissioning in Novosibirsk.
2. The strong surprises aren’t observed and the cooler are ready to assembly and commissioning in COSY.
3. The strong longitudinal field is useful for the electron beam transportation.
